Dynamic Memory Allocation

Course Evaluation

- Please take a few moments to fill out the course evaluation survey below:
- https://uri.campuslabs.com/eval-home/
 - ✓ On Piazza

The **new** and **delete** operators

- Used to create and destroy variables, objects, or arrays while the program is running
- Memory allocated with the new operator does NOT use the call stack
 - new allocations go into the **heap** (area of memory reserved for dynamic memory allocation)
- Programmer must destroy all variables, objects, and arrays created dynamically
 - √ using the delete operator

Heap vs Stack

- Dynamic (heap) memory
 - ✓ allocated during run time

 - must use pointers
 - ✓ alternative to local stack memory
- Static (stack) memory
 - exact size and type of memory must be known at compile time.
 - local variables are allocated automatically when a function is called and they are deallocated automatically when the function exits.

When do we need dynamic memory?

- · When you need a lot of memory.
 - ✓ Typical stack size is 1 MB, so anything bigger than 50-100KB should better be dynamically allocated, or you're risking crash.
- · When the memory must live after the function returns.
 - ' Stack memory gets destroyed when function ends, dynamic memory is freed when you want.
- Size that is unknown at runtime
 - ✓ When you're building a structure (like array, or graph) that dynamically changes or is too hard to precalculate.
- · Allocate storage space while the program is running
 - We cannot create new variable names "on the fly"

Then why does this work?

- There is a GCC extension to the standard that makes this work
- Not part of the standard C++ specification, but it is supported by some compilers as an extension from the C99 standard of the C language.

```
int n = 0;
int i = 0;
std::cout << "Enter size: ";
std::cin >> n;
int myarray[n];
for (i=0; i<n; i++)
{
    myarray[i] = i;
}</pre>
```

#include <iostream>
int main() {
 int *p1, *p2;

 p1 = new int;
 *p1 = 10;
 p2 = p1;
 *p2 = 20;
 p1 = new int;
 *p1 = 30;

 std::cout << *p1 << ' ' << *p2 << '\n';

 delete p1;
 delete p2;

 return 0;
}</pre>

Tracing the code Print output (drag lower right corner to resize) C++ (gcc 4.8, C++11) **EXPERIMENTAL!** known limitations 30 20 1 #include <iostream> Stack Heap 3 int main() { int *p1, *p2; main array p1 p1 = new int; >20 *p1 = 10;p2 p2 = p1;array 9 *p2 = 20; 10 p1 = new int; 30 11 *p1 = 30;12 std::cout << *p1 << ' ' << *p2 << '\n'; → 13 14 → 15 delete p1; 16 delete p2; 17 18 return 0; 19 }

                                                              today
40
                                                                                 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
41
       // creating an object
       Date *today = new Date(11, 18, 2019);
44
       (*today).print();
                                                                                   month 11
       // delete all allocated objects
       delete p;
        delete [] array;
                                                                                     year 2019
       delete today;
                                                                                     day 18
       return Θ;
                                          http://pythontutor.com/cpp.html#mode=edit
```

```
int size = 5;
int * list = new int[size];
for(int i =0; i < 5; i++){
    list[i] = i;
}

/// need to add more space later on
int * temp = new int[size + 5];
for (int i = 0; i < size; i++){
    temp[i] = list[i];
}

delete [] list; // this deletes the array pointed to by "list"
    list = temp;

https://pythontutor.com</pre>
```

Pointers and objects

Data members and methods of an object can be accessed by dereferencing a pointer

```
Date *today = new Date(11, 18, 2019);
(*today).print();
```

• Or ... can use the **-> operator**

```
Date *today = new Date(11, 18, 2019);
today->print();
```

malloc()/free()

malloc()

- The function malloc() is used to allocate the requested size of bytes and it returns a pointer to the first byte of allocated memory. It returns null pointer, if fails.
- · Here is the syntax of malloc() in C++ language,

```
pointer_name = (cast-type*) malloc(size);
pointer_name - Any name given to the pointer.
```

- **cast-type** The datatype in which you want to cast the allocated memory by malloc().
- **size** Size of allocated memory in bytes.

```
float* ptr = (float *) malloc (10 * sizeof(float));
```

free()

- The function free() is used to deallocate the allocated memory by malloc(). It does not change the value of the pointer which means it still points to the same memory location.
- Here is the syntax of free()

```
void free(void *pointer_name);
```

• **pointer_name** – Any name given to the pointer.

```
free(ptr);
```

Malloc/Free in use

```
int main() {
    int n = 4, i, *p, mystery = 0;
    p = (int*) malloc(n * sizeof(int));
    if(p == NULL) {
        std::cout << ("Error! memory not allocated.");
    }
    std::cout << ("Enter elements of array : ");
    for(i = 0; i < n; ++i) {
        std::cin >> (*p);
        mystery += (*p);
        p++;
    }
    std::cout << (sum);
    free(p);
    return 0;
}</pre>
```

Dangling Pointers

Dangling Pointers

- Pointer remains allocated but pointed to memory is deallocated.
- Remember: The pointer is statically allocated, but the memory it's pointing to is dynamically allocated.

 Print output (drag lower right corner to resize)

```
Dangling Pointer!
int* ptr = new int;
delete ptr;

// Memory is deallocated, but `ptr` still holds the address.

// Accessing it is undefined behavior:
std::cout << *ptr; // Undefined behavior!

// Safer approach:
ptr = nullptr;</pre>
```

Memory Leaks

Memory Leak

- Pointer is deallocated but pointed to memory is remains allocated.
- That memory is no longer in use by the program. So that memory location is reserved for no reason.
- · Opposite of a dangling pointer

22

Memory Leak void my_func() { int *data = new int; *data = 50; } void my_func() { int *data = new int; *data = 50; delete data; }

Destructors

Destructor

- Special `method` automatically called when objects are destroyed
 it is used to delete any memory created dynamically
- Objects are destroyed when ...
 - ... they exist in the stack and go out of scope
 - ... they exist in the heap and the delete operator is used
- A destructor ...
 - ... is a member function (usually public)
 - $\checkmark \dots$ must have the same name as its class preceded by a \sim
 - ... is automatically called when an object is destroyed
 - ... does not have a return type (not even void)
 - ✓ ... takes no arguments

Destructor Syntax

```
//Syntax for defining the destructor within the class
~ <classname>()
{
//body
}

//Syntax for defining the destructor outside the class
<classname>::~<classname>()
{
//body
}
```

2

Destructor Syntax

```
class Test
{
    public:
        Test()
        {
             std::cout<<"\n Constructor executed";
        }
        ~Test()
        {
                 std::cout<<"\n Destructor executed";
        }
};
int main(){
    Test t,t1,t2,t3;
    return 0;
}</pre>
```

Destructor Syntax

```
Test()
              std::cout<<"\n Constructor executed";</pre>
         ~Test()
              std::cout<<"\n Destructor executed";</pre>
int main(){
                                Constructor executed
                               Constructor executed
                                Constructor executed
    Test t,t1,t2,t3;
                               Constructor executed
    return 0;
                               Destructor executed
                                Destructor executed
                               Destructor executed
                               Destructor executed%
                               michaelconti@Michaels-MacBook-Pro-2 Desktop %
```

Try it

Write a program that stores the GPA of n number of students using dynamic memory.
